Problem

- Generalized background subtraction:** background subtraction for videos captured by a moving camera

Our method

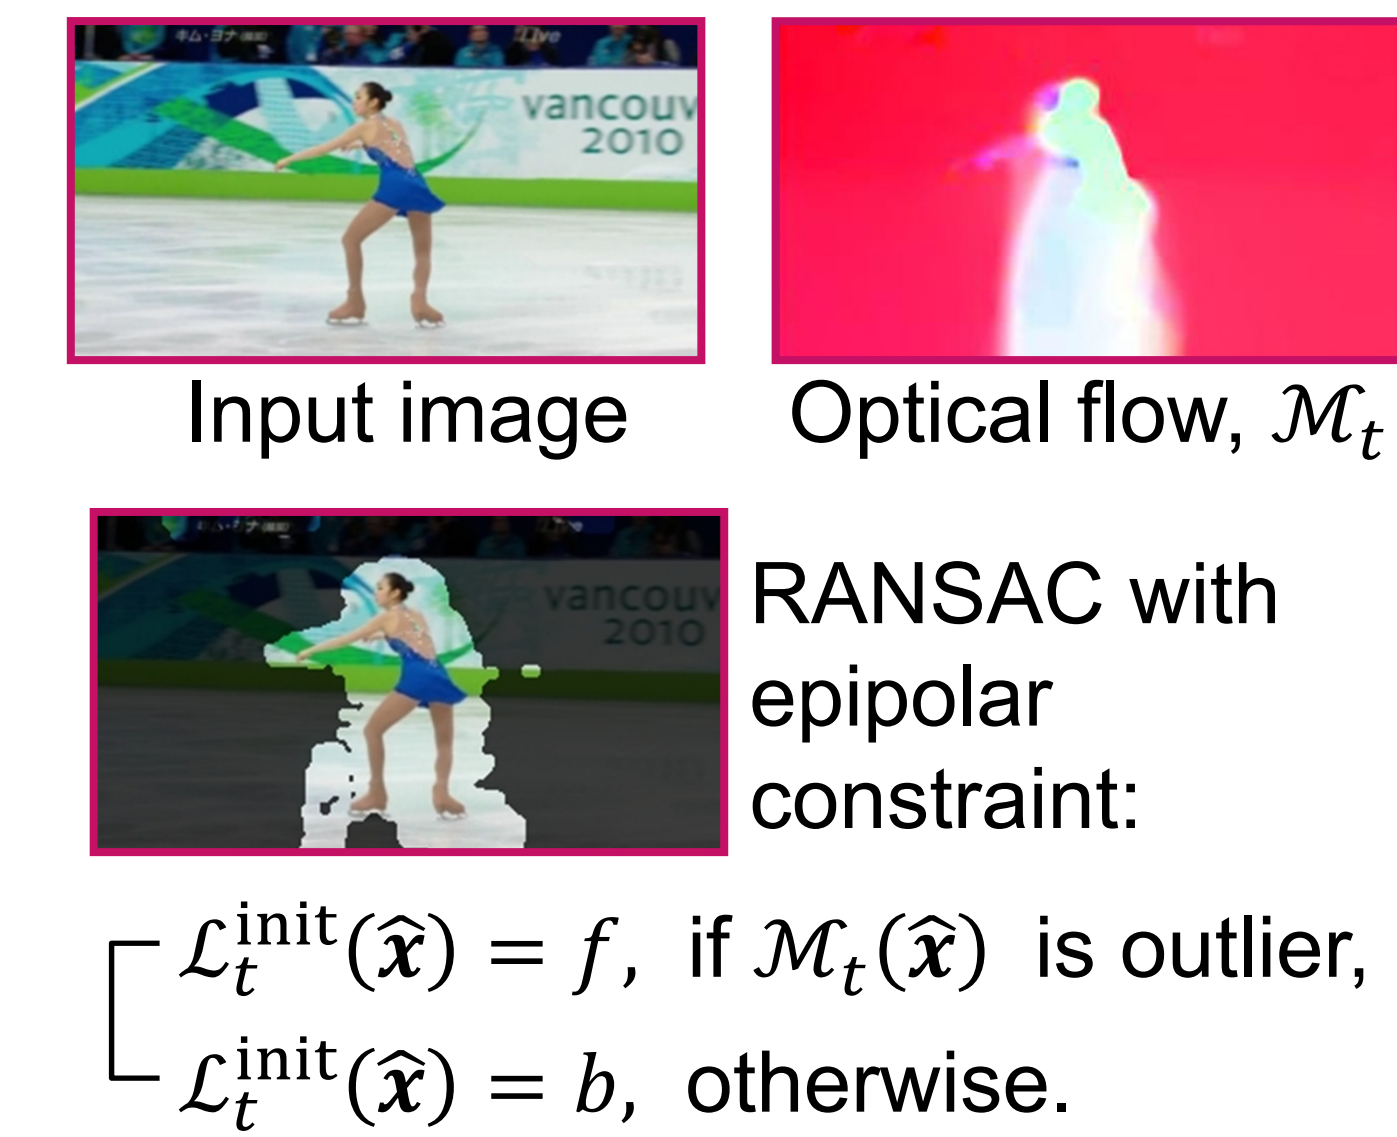

- Probabilistic inference for motion models, which is insensitive to noises and occlusions
→ *Nonparametric belief propagation (NBP)* [1]
- Reliable appearance estimation by **prediction via motion** and update with current observations
→ *Sequential Bayesian filtering*

Initial Pixel-Labeling

Motion segmentation

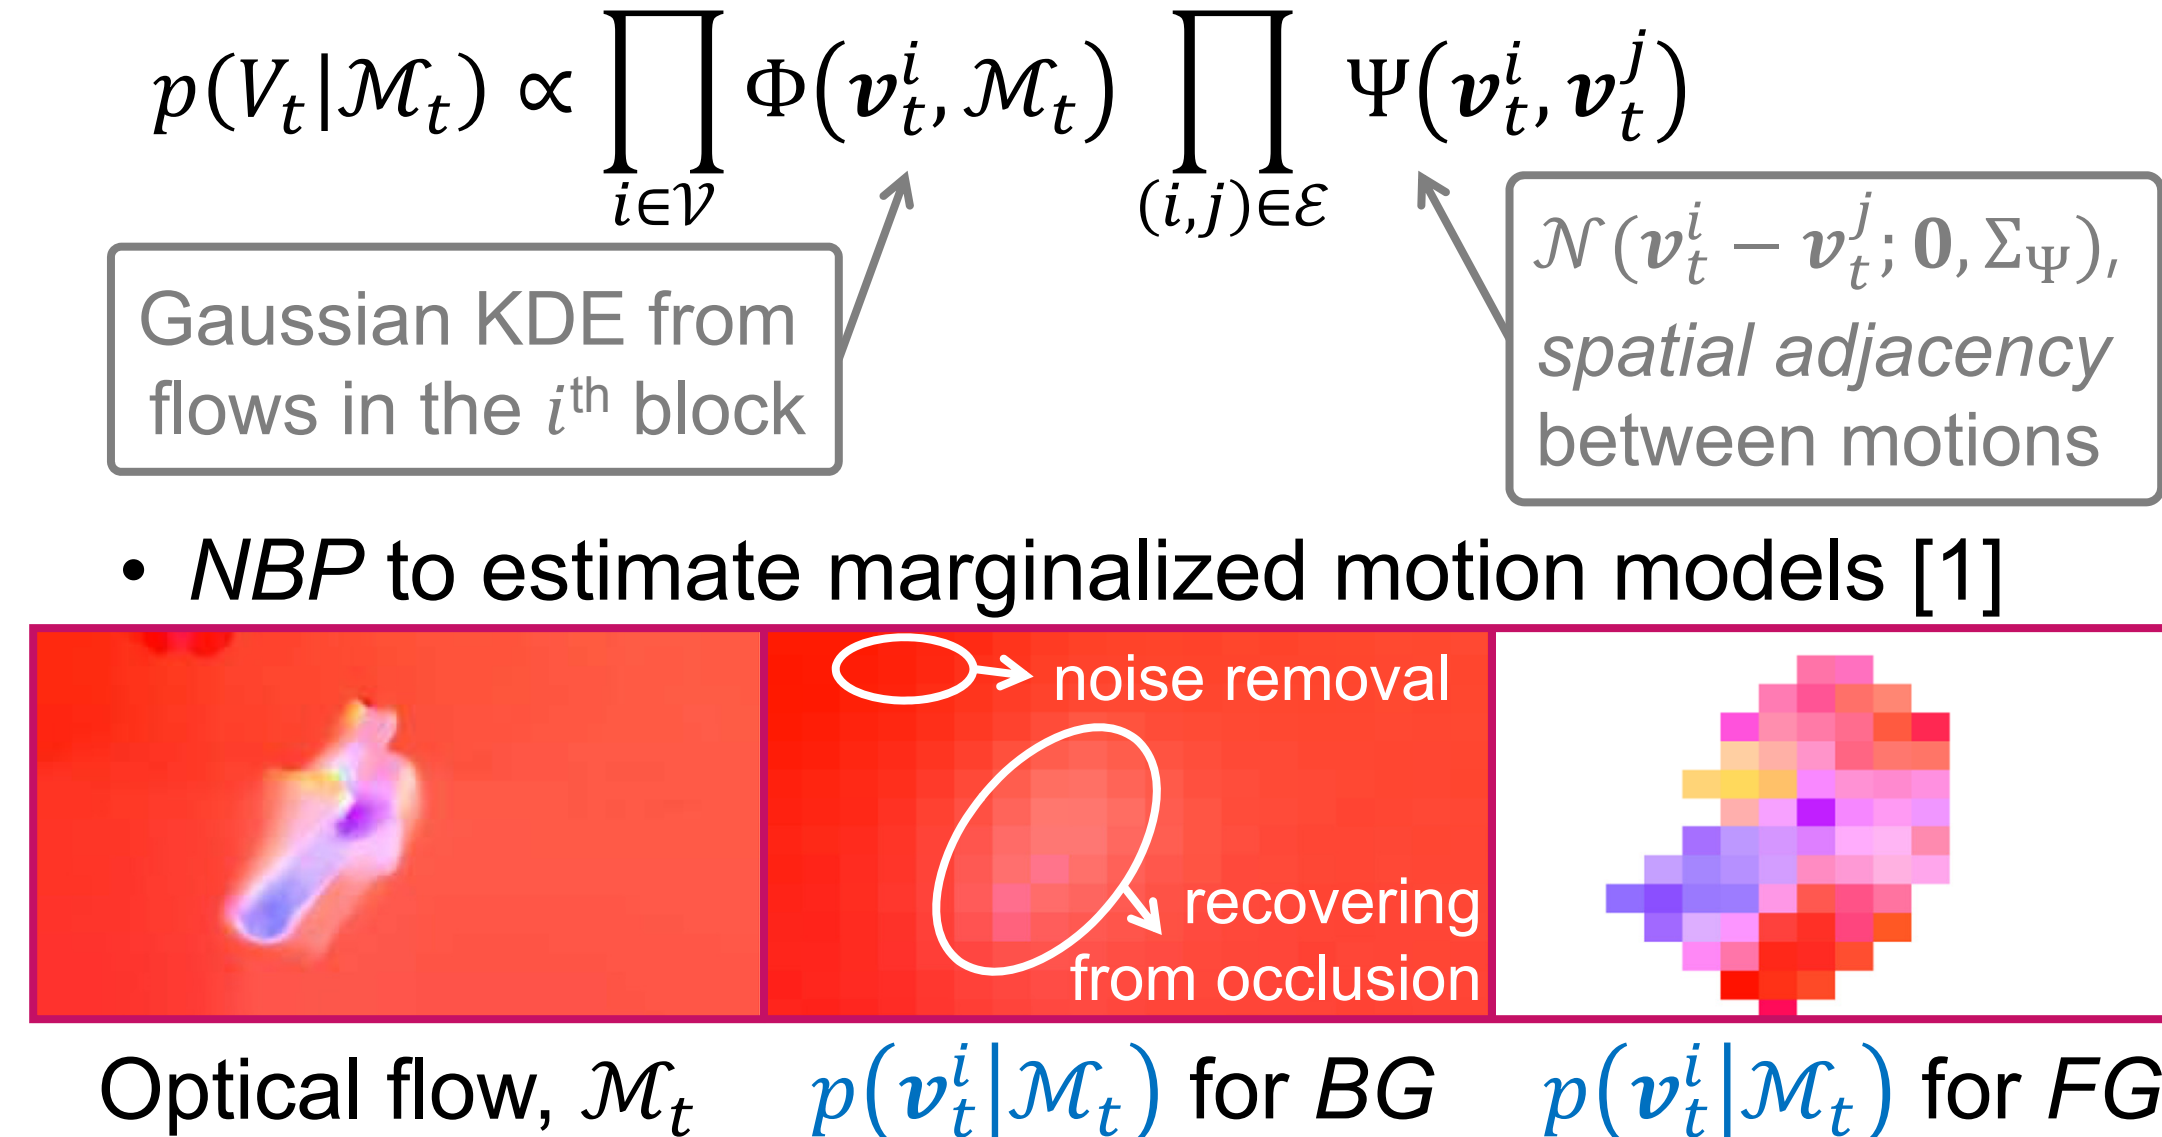

- Optical flow + epipolar const.

Motion Estimation by NBP

NBP in a four neighborhood MRF

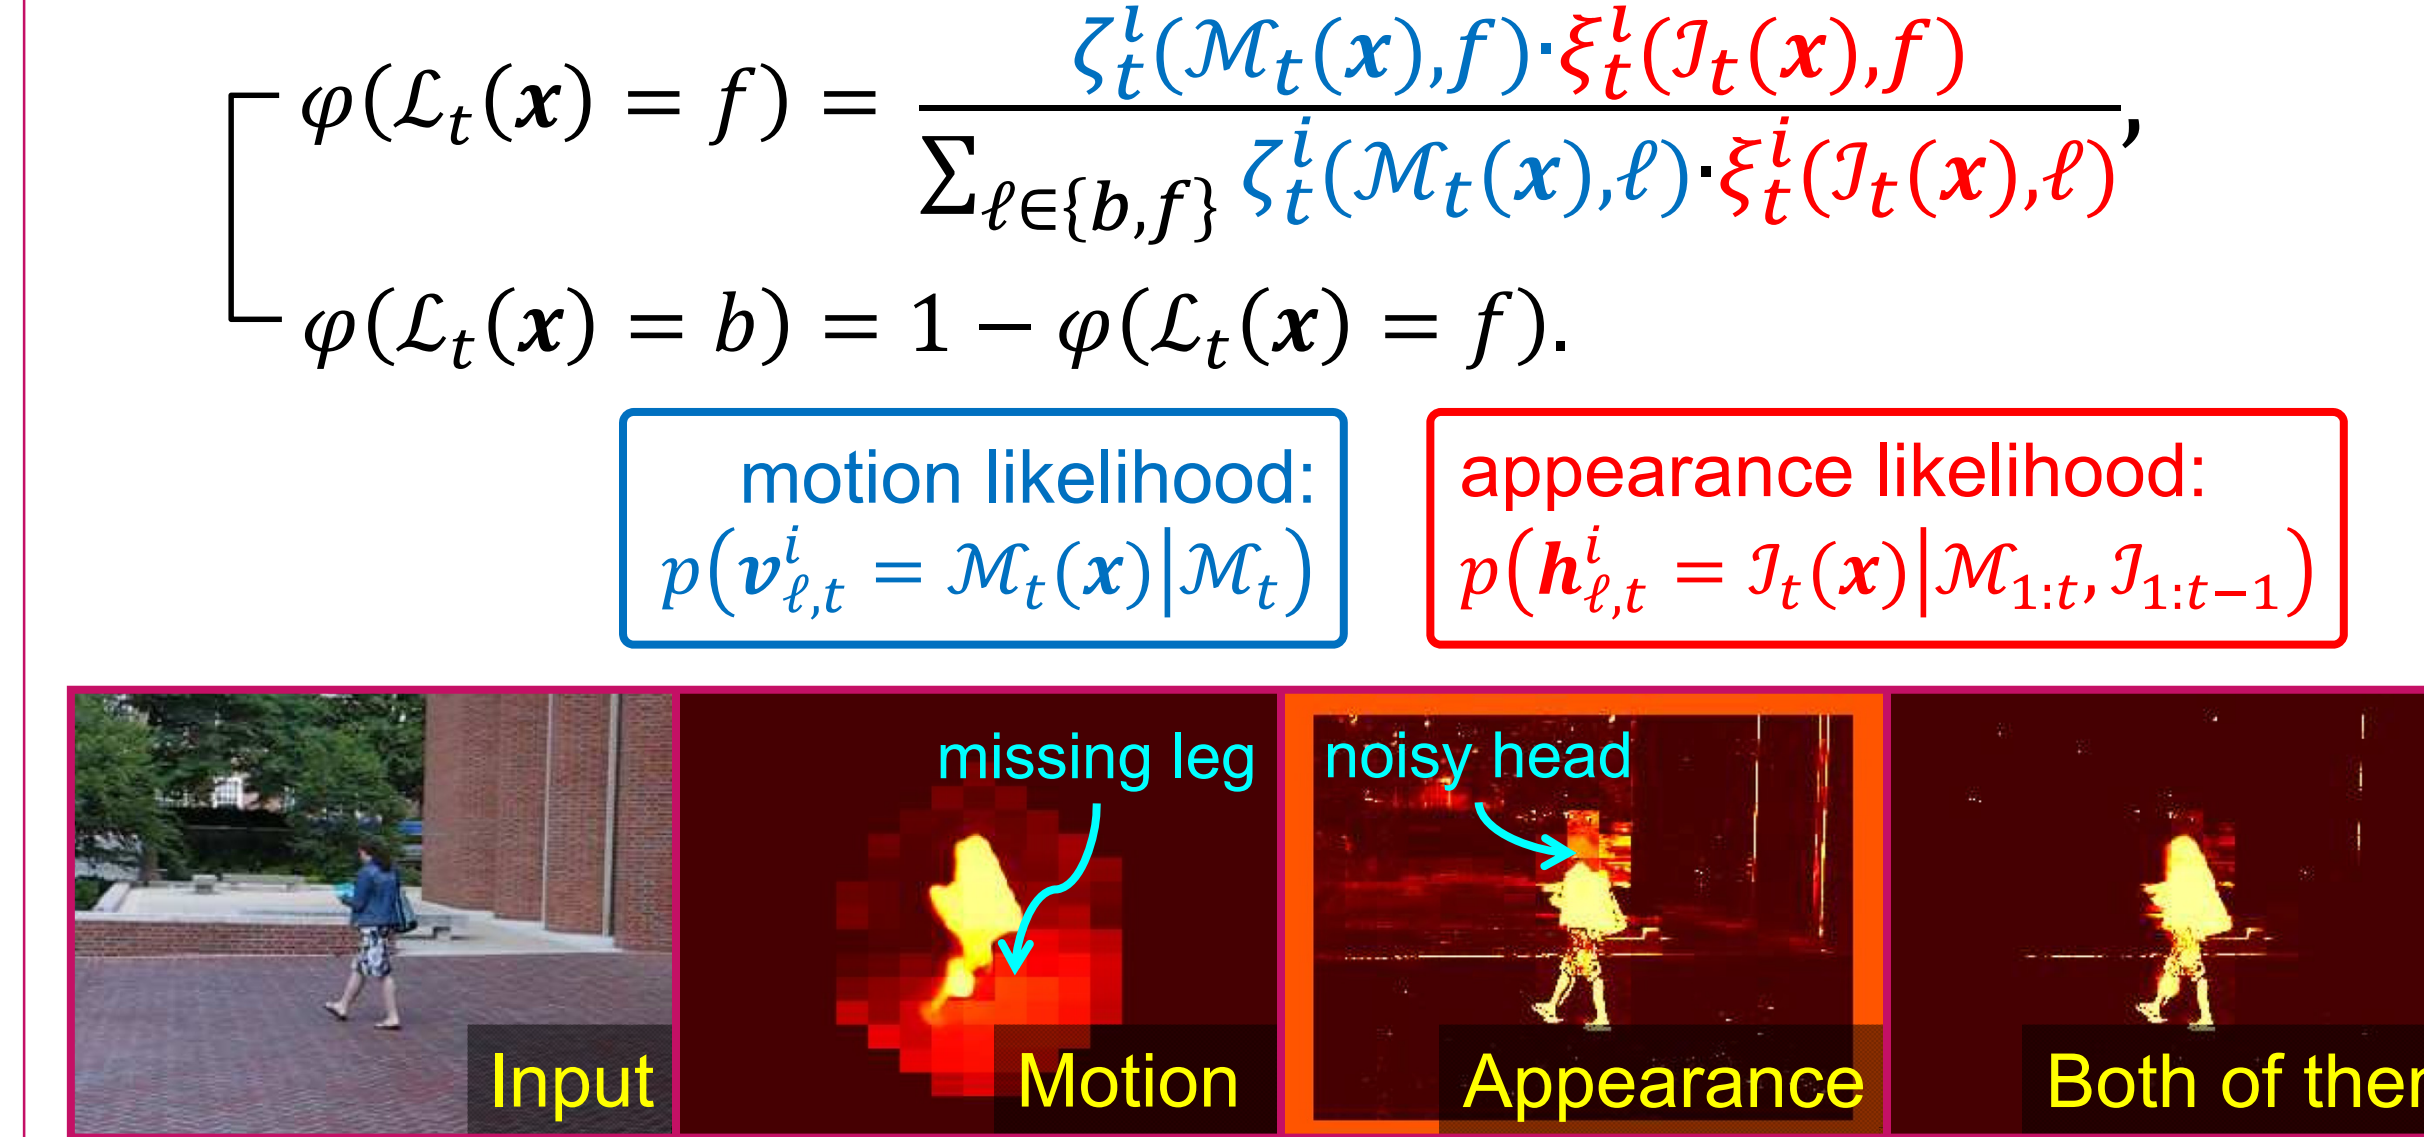

- Joint posterior probability w.r.t. the motion models

Pixelwise Label Estimation

Pixelwise belief propagation for binary labeling [2]

- Observation clique potentials

Appearance Prediction via Motion

Mixture of predictions

- Given a backward motion \hat{v}_t^i , appearance prediction for the i^{th} block at time t is given by

$$p(h_t^i | \hat{v}_t^i, \mathcal{M}_{1:t-1}, J_{1:t-1}) = \sum_{k=1}^N \gamma_k^i(\hat{v}_t^i) \cdot p_k(h_t^i | \mathcal{M}_{1:t-1}, J_{t-1}).$$

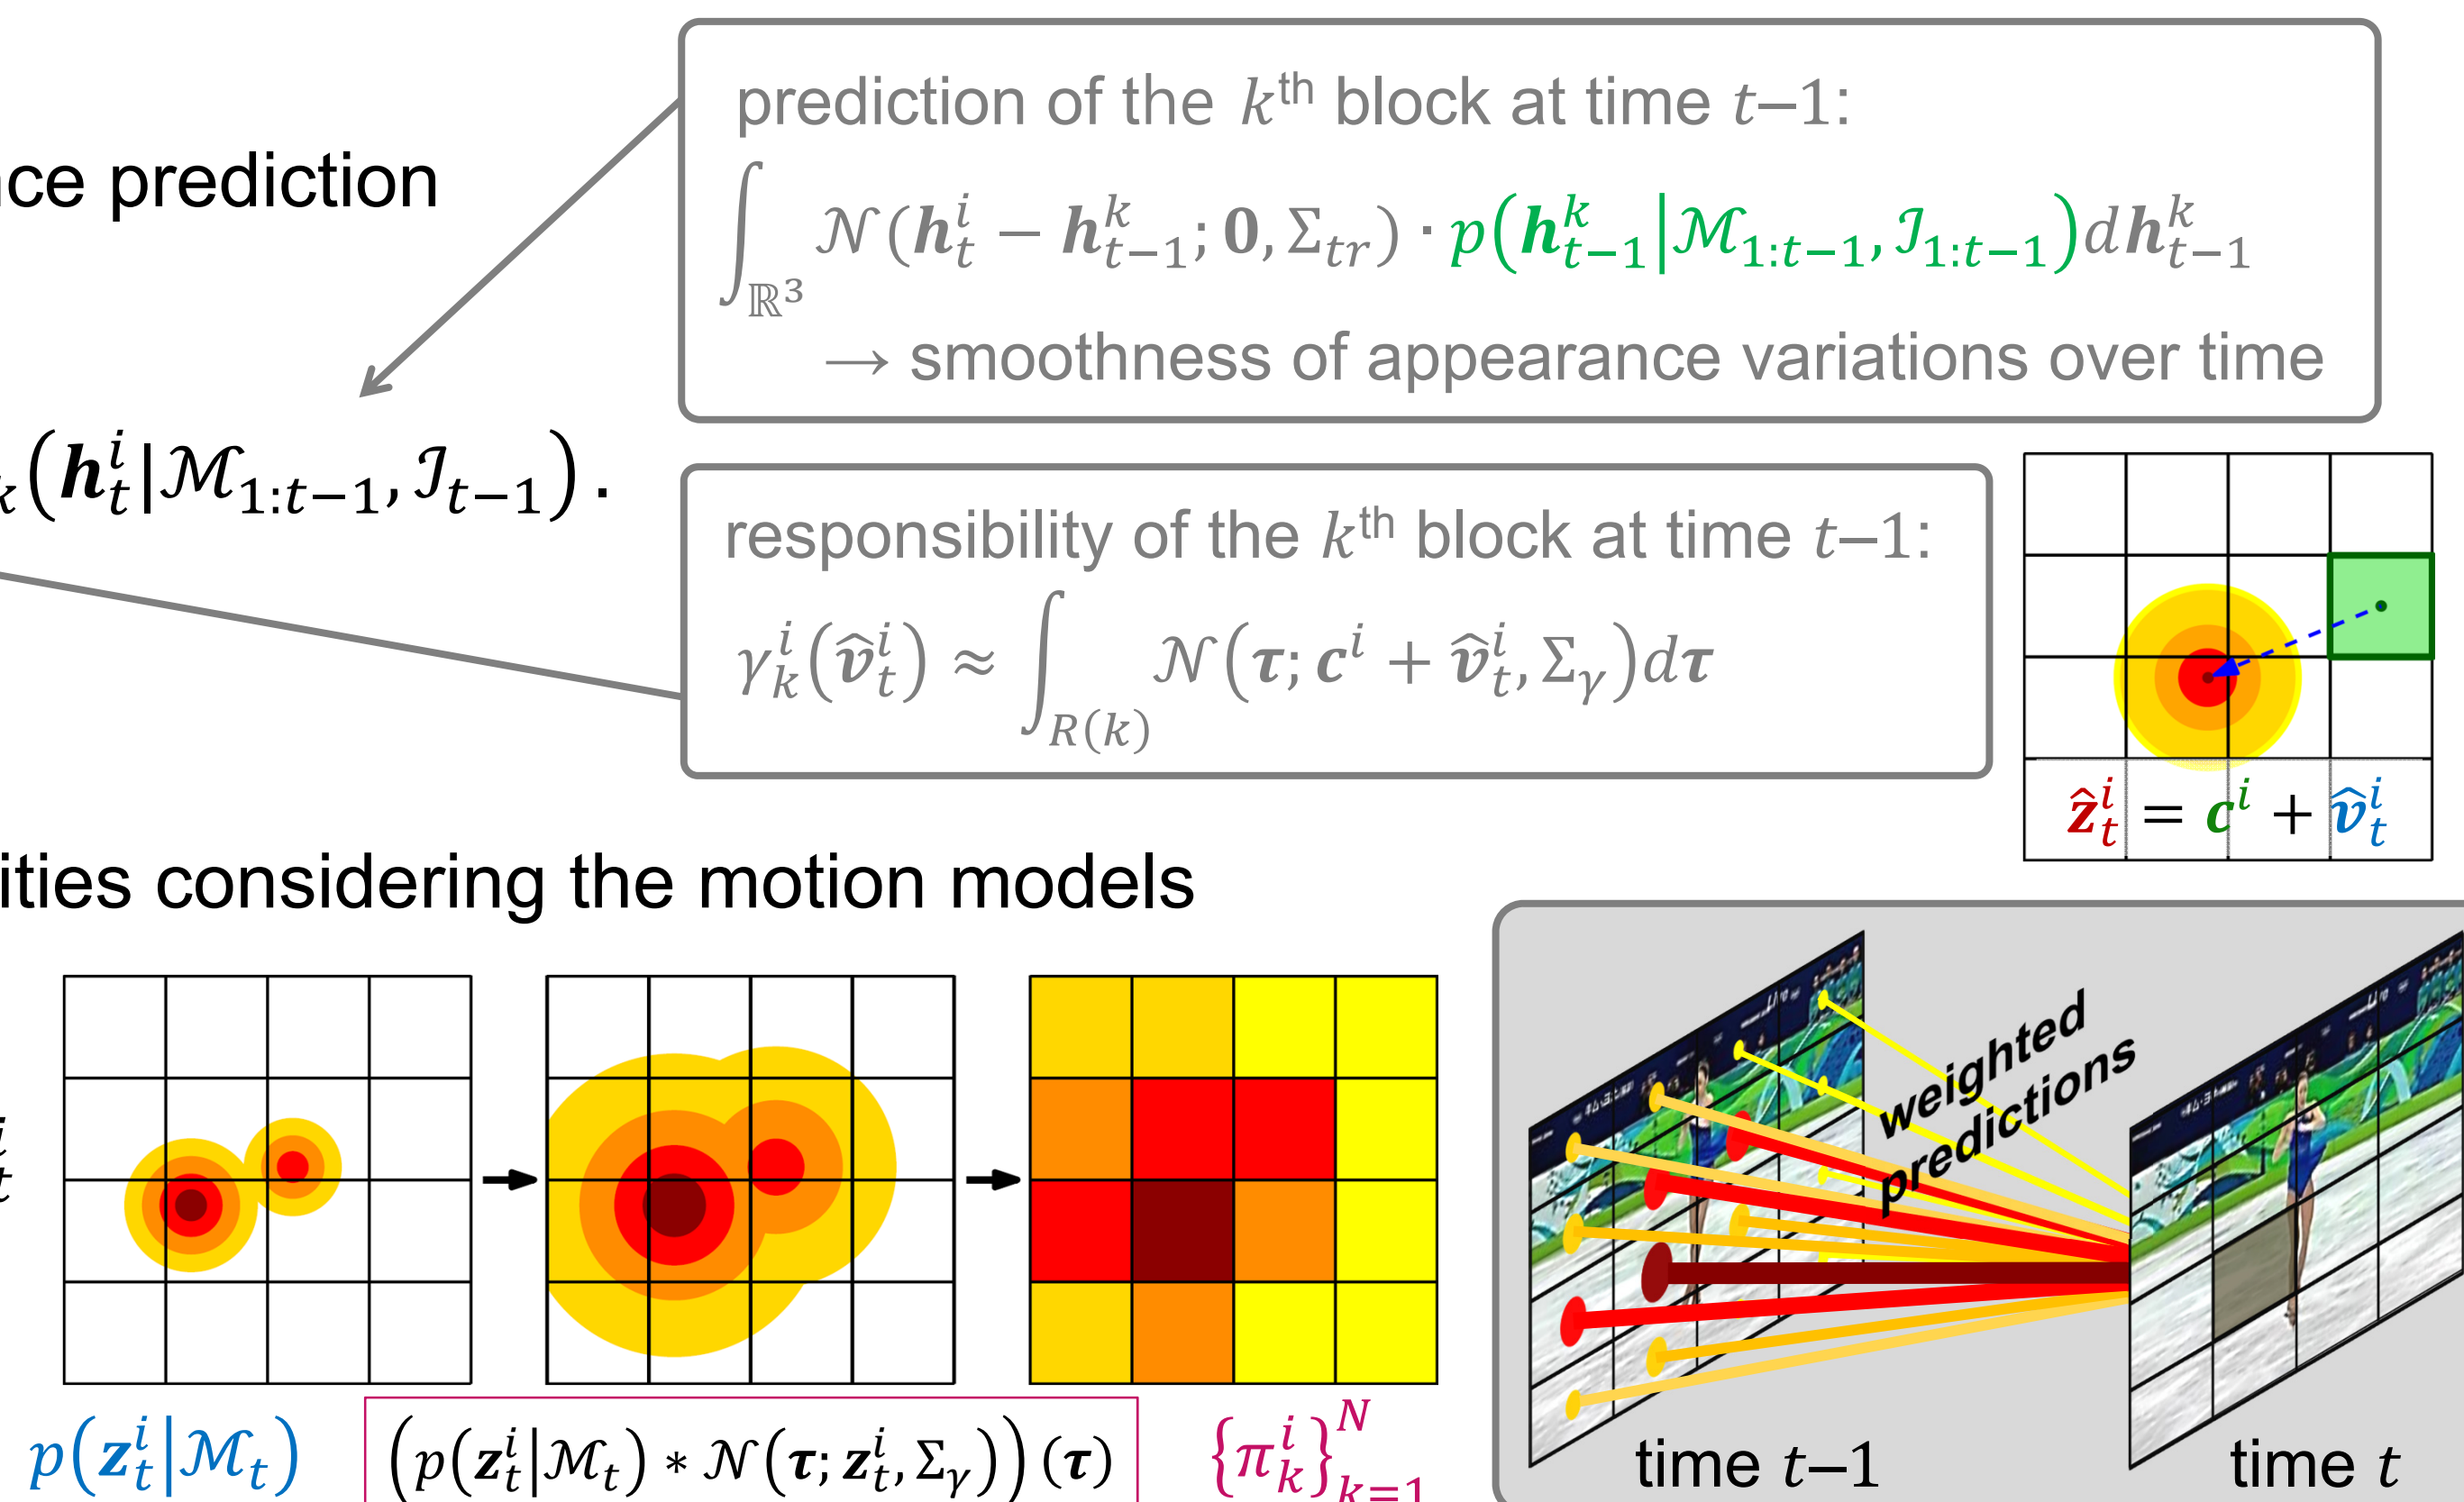

Appearance prediction via motion

- Mixture weights = expected responsibilities considering the motion models

$$p(h_t^i | \mathcal{M}_{1:t}, J_{1:t-1})$$

$$= \int_{\mathbb{R}^2} p(h_t^i | v_t^i, \mathcal{M}_{1:t-1}, J_{1:t-1}) \cdot p(v_t^i | \mathcal{M}_t) dv_t^i$$

$$= \sum_{k=1}^N \pi_k^i \cdot p_k(h_t^i | \mathcal{M}_{1:t-1}, J_{t-1})$$

Appearance Estimation by Bayesian Filtering

Update the prediction by observation

$$p(h_t^i | \mathcal{M}_{1:t}, J_{1:t}) \propto p(J_t | h_t^i) \cdot p(h_t^i | \mathcal{M}_{1:t}, J_{1:t-1})$$

Experiments

■ Ours ■ Ours without motion inference ■ Motion segmentation ■ [Sheikh et al., ICCV'09] with optical flow
